

PREVALENCE AND SPECIES OF *Fasciolopsis buski* IN VIETNAM

Nguyen Van De and Pham Ngoc Minh

Hanoi Medical University, Hanoi Vietnam

Abstract

PURPOSE: To report prevalence and species of *Fasciolopsis buski* in Vietnam.

METHOD: Stool examination by Kato-Katz technique for detection prevalence of fasciolopsiasis, and identification species by morphology and molecular method.

RESULT: On 10,540 stool samples were examined in 14 provinces and adult worms of *Fasciolopsis* collected from patients in other 3 provinces. The result showed that 13/14 provinces have been patients infected *Fasciolopsis*. However, fasciolopsiasis was determined distribute in 16 provinces with prevalence of 1.23% in average (from 0.16% to 3.82%). Adult worms were identified as *Fasciolopsis buski* by morphology and confirmed by molecular analysis using of 1950 bp-18S ribosomal RNA(18S rRNA) as genetic marker.

Introduction

Plant-borne Trematode has been found six species to affect humans: *Fasciola hepatica*, *Fasciola gigantica*, *Fasciolopsis buski* (in Fasciolidae family), *Gastropiscoides hominis* (in Gastrodiscidae family) and *Watsonius watsoni*, *Fischoederius elayatus* (in Paramphistomidae).

Fasciolopsiasis is common fluke causing by *Fasciolopsis buski*. This disease is found in Central and Southern China, Taiwan, Banladesh, India, Vietnam, Thailand, Laos and some other foci in South East Asia and affect some 10 million people.

Foodborne trematode is common in Vietnam as *Clonorchis/Opisthorchis* in more than 32 province (prevalence is highest of 37%), Heterphyidae/Echinostomatidae in more than 18 provinces (prevalence is highest of 53.4%), *Paragonimus* in more than 10 provinces (prevalence is highest of 15%) (Nguyen Van De et al, 1996, 2003, 2006). *Fasciola gigantica* was the first report in 1928 (Codville et al, 1928) and during 1997 to 2012, *Fasciola gigantica* distibuted in more than 52 provinces. *Fasciolopsis buski* was the first report in 1908 (Barrios and Noc, 1908) and during 2000 to 2006, *Fasciolopsis buski* was determined distribution in more than 16 provinces (in this report).

Methodology

Human prevalence surveys: Fasciolopsiasis survey in community is used methods stool examination by Kato-Katz technique.

Identification of the species: Adult worms collected from patients for identification of species by morphology and molecular methods.

Identification of *Fasciolopsis spp* used 18S Ribosome genom. Total genomic DNA was extracted from the adult worms using a DNAeasy Tissue Kit (Quagen). A 1,950 bp fragment of 18S rDNA was amplified by polymerase chain reaction (PCR) using conserved oligonucleotide primer. After purification, PCR products were cloned using a TA Cloning Kit (Intrgen) and plasmids was extracted using QIAprep Spin Miniprep Kit (Qiagen). DNA inserts was subsequently sequenced using T7 and M-13 reverse primers and an ABI 377 automated DNA sequencer and BigDye sequencing chemistry (ABI, Foster City, CA, USA). The sequences was aligned with a sequence for *Fasciolopsis buski* 18S rDNA deposited in the GenBank database (Accession No.L06668).

RESULTS

*Prevalence of *Fasciolopsis* by province*

Table 1. The result of stool examination of *Fasciolopsis buski* egg by Kato-Katz technique

No	Study site (province)	No examine	Result of stool examination	
			Infected people	% infection
1	Yen Bai	499	2	0.40
2	Tuyen Quang	704	4	0.57
3	Cao Bang	492	1	0.20
4	Bac Kan	627	2	0.32
5	Phu Tho	604	7	1.16
6	Quang Ninh	545	3	0.55
7	Bac Giang	686	5	0.73
8	Ha Tay	603	3	0.50
9	Nam Dinh ^a	615	5	0.81
10	Thanh Hoa ^a	558	17	3.05
11	Nghe An ^a	1,376	14	1.02
12	Ha Tinh	724	0	0
13	Dak Lak	1,494	57	3.82
14	An Giang ^a	1,013	10	0.97
Total		10,540	130	1.23

Remark: ^a adult worms collected from this province for identification species.

On 10,540 human stool samples were examined by Kato-Katz technique in 14 provinces. The result showed that *Fasciolopsis* infection rate of 1.23% in average and one of 14 provinces no case (Tab 1). Beside 14 above provinces for stool examination, there are 3 provinces, which were Ninh Binh^a, Thua Thien - Hue^a and Can Tho^a, where determined fasciolopsiasis patients, who collected adult worms for identification (from all above provinces, adult worms collected from 7 provinces).

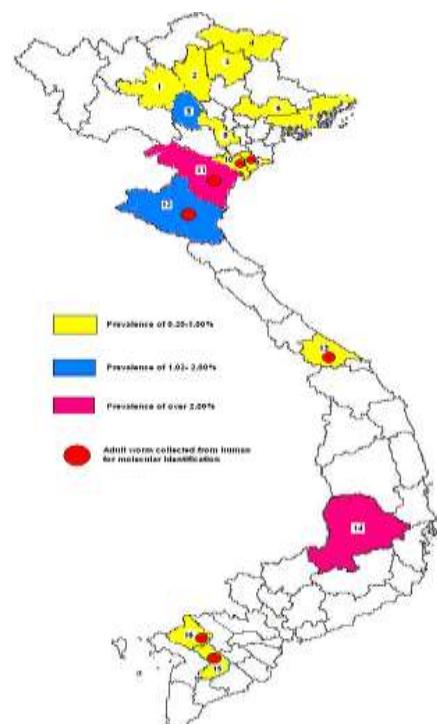

Figure 1: Distribution of *Fasciolopsis buski* by province in Vietnam up to 2006

Identification of *Fasciolopsis* adult worms from patients.

Adult worms from patients in 7 provinces were identified by morphology and confirmed by molecular method as follow:

Identification species by morphology

Adult worms of *Fasciolopsis* are pink color, average body size was 12.5 mm in length and 5.5 mm in width. Oral sucker of 0.5 mm and ventral sucker of 1.5 mm. There are 2 testes, which are highly branched, located one behind the other in the posterior region of the body, the ovary is also branched and is located in front of the testes to the right of the mid-line of the body, whilst the vitellaria are located laterally from the anterior to the posterior. The intestine is turning and to the end of the body. Melite form is big and located in the central body (Fig 2).

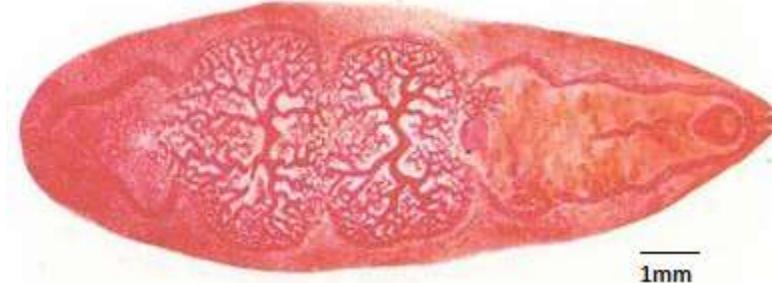

Figure 2. A adult of *Fasciolopsis buski* collected from patient

Identification species by molecular method

Table 2: List of adult worm samples collected from patients for molecular identification

Morphology	Code	Local origin	Form sample
<i>Fasciolopsis</i> sp	FspNDHuma	Nam Dinh	Adult worm
<i>Fasciolopsis</i> sp	FspNBHuma	Ninh Binh	Adult worm
<i>Fasciolopsis</i> sp	FspTHHuma	Thanh Hoa	Adult worm
<i>Fasciolopsis</i> sp	FspNAHuma	Nghe An	Adult worm
<i>Fasciolopsis</i> sp	FspHHuma	Thua Thien-Hue	Adult worm
<i>Fasciolopsis</i> sp	FspCTHuma	Can Tho	Adult worm
<i>Fasciolopsis</i> sp	FspAGHuma	An Giang	Adult worm

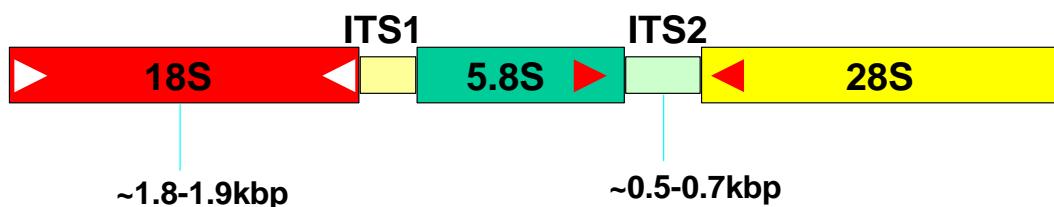

Figure 3: Ribosome genom (18S, 5.8S and 28S) and internal transcribed spacer (ITS1, ITS2). 18S (length of 1.8-1.9kbp) and ITS2 (length of 0.5-0.7kbp) are important molecular makers for study of identification of species.

Total of 18S Ribosome (18S rARN) genome (1950 nucleotide pairs) of adult worms of *Fasciolopsis* from patients in Nam Dinh, Ninh Binh, Thanh Hoa, Nghe An, Thua Thien-Hue, Can Tho and An Giang provinces (Table 2) were sequenced and compared with this genome of *Fasciolopsis buski* in Gen Bank. The result showed that nucleotide genome sequences of 18S rARN from all study samples were similarly (100%) and compared with 18S rARN of *Fasciolopsis buski* in Gen Bank (code number: L06668), they differ only in two nucleotides (2/1950 nucleotides), the difference rate of 0.01%. However, Vietnamese *Fasciolopsis* from patients is *Fasciolopsis buski* and published in Gen Bank with code number AY 311386, AY618841, AY618842 and AY618843 (Fig. 3).

Conclusion

Prevalence of Fasciolopsiasis in 16 provinces of the country in Vietnam with 1.23% and adult flukes collected from patients were identified as *Fasciolopsis buski* using morphology and molecular method.
